**Better Card****S44767\_en**

---

Write a **function** that, given two Poker cards, returns `true` if the value of the first card is higher than the value of the second card. The cards are from the usual Poker deck, represented by one of the following 13 characters: A, 2, 3, ..., 9, 0, J, Q, K. There are two special characters: the card A is the Ace and is equivalent to 1, as in normal decks, and the digit 0 represents 10, for simplicity. Note that the cards identified by a letter are always uppercase.

The values of the cards are as follows: the numeric cards have the value indicated by their number. The card 0 will have the value 10, as it represents the card 10. Next, the J is worth 11, the Q is worth 12, and the K is worth 13. The A would be worth 1, but in this problem, we will consider it to have the highest value (as is often the case), and it will be 14.

The function header is exactly:

```
/**  
 * @pre c1, c2 in {A, 2, 3, ..., 8, 9, 0, J, Q, K}  
 * @post Returns true if c1 has a higher value than c2  
 */  
bool better_card(char c1, char c2);
```

**Observation**

You only need to submit the requested function; the main program will be ignored.

**Problem information**
